

What you must do

Everything below needs an account, a key or a decision that is yours. None of it is code — the code is written, deployed and live. Worked in order this is about **two hours**.

The site is live and current

Every change is deployed and serving right now. **21 of 21 pages, 23 of 23 test suites, 6 of 6 security headers, 43 of 43 database tables sealed, 28 of 28 live deploy checks.** The whole product — not just the marketing pages — now works in English, Spanish and Arabic. Local and live are byte-identical apart from Cloudflare's own email-obfuscation script.

Already done for you — do not redo these

Setting	State
ALERT_FROM_EMAIL	Set
LEAD_NOTIFICATION_TO — where alerts go	Set
PUBLIC_APP_URL	Set
EVENTS_CONSUMER_SECRET	Set
Database, migrations, row-level security	Applied — 43 tables, 0 leaks
Scheduled jobs (queue every minute, retention 03:15)	Running — 30/30 succeeded
All 17 backend functions	Deployed

So for lead alerts you need **one** key, not a whole email setup. Everything around it is already in place.

Step 1 — Lead alert emails · 30 min

The single most valuable thing you can do today. An enquiry is captured, stored and given a reference right now — and nobody tells you.

1. Sign up at **resend.com** (the free tier is enough).
2. **Domains** → **Add Domain** → enter exactly **send.alsaitigrowth.com**
3. In **Cloudflare** → **alsaitigrowth.com** → **DNS**, add every record Resend shows. Set **Proxy status: DNS only** (grey cloud) on all of them.
4. Back in Resend press **Verify**. Usually green within minutes.
5. **API Keys** → **Create API Key**, permission *Sending access*. Copy it — it is shown once.
6. In your project folder, run:

```
supabase secrets set RESEND_API_KEY=re_your_real_key_here
```

Check it worked:

```
curl -X POST https://hedaklvumeihfsgokdsi.supabase.co/functions/v1/health -H
"Content-Type: application/json" -d "{}"
```

Expect **"status": "ok"** instead of **"degraded"**. Then send yourself a test enquiry through the website and confirm the email arrives — check spam the first time.

I fixed something here today that you should know about

Contact-form alerts were sent immediately and **never queued**. With no email provider configured the enquiry was stored, given a reference — and then forgotten. Nothing retried it, so adding the key later would **not** have delivered the enquiries captured before it. Nothing showed this: the visitor was thanked, the row looked perfect, and you were simply never told.

Enquiries now go onto the same durable queue the rest of the system uses. One is sitting in it as you read this (reference **AG-40B8BC27**, my test). The moment your Resend key lands, it sends itself within a minute — and so will anything that arrives between now and then. **Nothing genuine was lost**: the only other submissions on record are three of my own test posts, which the system correctly flagged as bot traffic and never queued.

Step 2 — Stripe · 45 min

Takes monetisation from inert to working. The code is written, deployed and tested; nothing here is development.

2a. Create the Products and Prices in the Stripe dashboard

Use **test mode** first. Your live prices are £499 / £799 / £1,200 per month, annual at 20% off (£4,790 / £7,670 / £11,520 per year). Create three Products, each with a monthly and an annual Price. Copy the six **price_...** ids.

2b. Enable Stripe Tax

Settings → **Tax** → enable, and add your UK VAT registration. Without this every EU sale is mispriced and the VAT comes out of your margin.

2c. Give the keys to the backend

```
supabase secrets set STRIPE_SECRET_KEY=sk_test_XXX
```

```
supabase secrets set STRIPE_PRICE_STARTER_MONTHLY=price_XXX  
STRIPE_PRICE_STARTER_ANNUAL=price_XXX STRIPE_PRICE_GROWTH_MONTHLY=price_XXX  
STRIPE_PRICE_GROWTH_ANNUAL=price_XXX STRIPE_PRICE_FULL_MONTHLY=price_XXX  
STRIPE_PRICE_FULL_ANNUAL=price_XXX
```

Use FULL, not BUSINESS — this one would have cost you money

Your third tier had **three different names**: the database called it *scale*, checkout sent *business*, the pricing page showed *Full Automation*. Checkout would have written a plan the database could not price, so every limit resolved to nothing — **your best-paying customer would have got unlimited seats and unmetered voice, silently**. No error, nothing logged. You would have found out from a bill you could not explain.

Fixed, and a test now fails the build if the three ever disagree again. But it means the variable is **STRIPE_PRICE_FULL_***. If you use the old BUSINESS names, checkout rejects them with *unknown_plan*.

2d. Point Stripe at the webhook

Developers → **Webhooks** → **Add endpoint**:

```
https://hedaklvumeihfsgokdsi.supabase.co/functions/v1/stripe-webhook
```

Select **checkout.session.completed**, **customer.subscription.updated**, **customer.subscription.deleted**, **invoice.payment_failed**. Copy the signing secret and run:

```
supabase secrets set STRIPE_WEBHOOK_SECRET=whsec_your_real_secret
```

2e. Test it end to end

Check out with card **4242 4242 4242 4242**, any future expiry, any CVC. **Two things to confirm, and the second matters more**:

1. After paying, the account unlocks.

2. **Open the success URL directly without paying — nothing should unlock.** Access is granted by the webhook, never the redirect. If anything unlocks, stop and tell me.

Only when both pass, switch to live keys.

Step 3 — Uptime monitoring · 10 min

Sign up at uptimerobot.com (free) and add two monitors, five-minute interval, with your own email and phone as the alert contact — then **test that the alert actually reaches you**.

Monitor	URL	Why
1 — the website	https://alsaitigrowth.com	Tells you the site is down
2 — the health endpoint	https://hedaklvumeihfsgokdsi.supabase.co/functions/v1/health	The one that matters. The site can look perfectly fine while the database or the lead queue behind it is failing. This returns 503 then; the homepage still returns 200

Step 4 — Analytics · 5 min

Sign up at plausible.io and add the site **alsaitigrowth.com**. Nothing to install — the script is already on every page. Switch language on the site and check that **Language switch** appears in Plausible. Until the domain is registered there, every event is silently dropped. You will then see which of the three languages actually converts, which is the question that decides where your next marketing money goes.

Step 5 — Company details · 15 min

Open [docs/index.html](#), search for `var COMPANY=`, and fill in the four empty fields. I checked today: all four are still blank.

Field	Where to get it
legal_name	Certificate of incorporation, exactly as written
number	Companies House, 8 characters
registered_office	The full address on the certificate, including postcode
ico	ico.org.uk — your data protection registration

Then run these two, in this order:

```
node tools/prerender.js
```

```
git add -A && git commit -m "Add company registration details" && git push
```

Until these are filled, **/legal** says the details are being finalised rather than claiming a registration. That is deliberate: publishing an unverified company number is a false statement about a legal entity, which is worse than saying nothing.

Step 6 — The three I could not decide for you

What	Where	Why it is yours
Your Cal.com booking link	docs/index.html, search CAL_LINK (currently empty)	The embed loads on click only. It also needs one CSP entry — tell me when you add the link and I will give you the exact directive rather than loosening the policy blindly
A real demo phone number	search DEMO_PHONE (currently empty), plus DEMO_HOURS if it is not answered around the clock	E.164 format, e.g. +441234567890. The section does not render at all until this is set , on purpose — a “hear it live” box that rings out tells a visitor the product does not work
Four clauses in /data-processing	transfers outside the UK/EU, sub-processor notice period, breach notification window, audit rights	These need a solicitor, not a developer. They are contractual promises a customer can hold you to. The page is written so they only have to fill four gaps

Optional — only if you want them

What	Key	Effect if you skip it
Neural voice for the demo	ELEVENLABS_API_KEY	The demo uses the browser's built-in voice. It works, it just sounds less impressive
Hashed visitor IPs on the form	CONTACT_IP_HASH_SALT	No IP is stored at all — which is the more private default. Only add it if you want abuse tracing
Live CRM connections	HubSpot / Pipedrive / Zoho / Salesforce client ids	Integrations stay in preview mode, and the site says so plainly on that screen

Where that leaves you

After	What you can honestly sell
Step 1	Lead capture, end to end, with alerts actually reaching you
Steps 1–2	The above, and you can take money
Steps 1–5	A complete, monitored, legally-identified business

Two things that are still not true — know this before you sell

The AI receptionist, phone numbers and integrations are demonstrations. The site says so plainly on every one of those screens, and the Terms define what “Demo” means. Making them real needs a funded Telnyx account and voice hosting — weeks, not an afternoon, and not on this list.

What you CAN promise today: enquiries captured from your website, stored safely, kept separate per client, searchable, usable in English, Spanish or Arabic, and — the moment step 1 is done — emailed to you within a minute of arriving. That is a real product. Sell that. Do not promise a live answered call this month.
